Unit Testing Framework

The Python unit testing framework, sometimes referred to as “PyUnit,” is a Python language version of JUnit, by Kent Beck and Erich Gamma. JUnit is, in turn, a Java version of Kent’s Smalltalk testing framework. Each is the de-facto standard unit testing framework for its respective language.

unittest supports test automation, sharing of setup and shutdown code for tests, aggregation of tests into collections, and independence of the tests from the reporting framework. The **unittest** module provides classes that make it easy to support these qualities for a set of tests.

Unit Testing Framework

To achieve this, `unittest` supports some important concepts:

- **test case:** A test case is the smallest unit of testing. It checks for a specific response to a particular set of inputs. `unittest` provides a base class, `TestCase`, which may be used to create new test cases.
- **test fixture:** A test fixture represents the preparation needed to perform one or more tests, and any associate cleanup actions. This may involve, for example, creating temporary or proxy databases, directories, or starting a server process.
- **test suite:** A test suite aggregate tests that should be executed together. It is a collection of test cases, test suites, or both.
- **test runner:** A test runner is a component which orchestrates the execution of tests and provides the outcome to the user. The runner may use a graphical interface, a textual interface, or return a special value to indicate the results of executing the tests.

Test Cases

Test cases are supported through the **TestCase** class;

```
import unittest

class TestStringMethods(unittest.TestCase):

    def test_upper(self):
        self.assertEqual('foo'.upper(), 'FOO')

    def test_isupper(self):
        self.assertTrue('FOO'.isupper())
        self.assertFalse('Foo'.isupper())

    def test_split(self):
        s = 'hello world'
        self.assertEqual(s.split(), ['hello', 'world'])
        # check that s.split fails when the separator is not a string
        with self.assertRaises(TypeError):
            s.split(2)
```

Test Cases and Asserts

A testcase is created by subclassing `unittest.TestCase`.

The test methods are defined with names starting with the string “test”. This naming convention informs the test runner about which methods represent tests.

The `TestCase` class provides several methods to check for and report code failures. Those methods are called **Asserts**. Using those methods, the test runner can accumulate all test results and produce a report.

Asserts

Some of the assert methods are the following:

Method	Checks that
<code>assertEqual(a, b)</code>	<code>a == b</code>
<code>assertNotEqual(a, b)</code>	<code>a != b</code>
<code>assertTrue(x)</code>	<code>bool(x) is True</code>
<code>assertFalse(x)</code>	<code>bool(x) is False</code>
<code>assertIs(a, b)</code>	<code>a is b</code>
<code>assert IsNot(a, b)</code>	<code>a is not b</code>
<code>assertIsNone(x)</code>	<code>x is None</code>
<code>assert IsNotNone(x)</code>	<code>x is not None</code>
<code>assertIn(a, b)</code>	<code>a in b</code>
<code>assertNotIn(a, b)</code>	<code>a not in b</code>
<code>assertIsInstance(a, b)</code>	<code>isinstance(a, b)</code>
<code>assertNotIsInstance(a, b)</code>	<code>not isinstance(a, b)</code>

Asserts

Some of the assert methods are the following:

Method	Checks that
<code>assertAlmostEqual(a, b)</code>	<code>round(a-b, 7) == 0</code>
<code>assertNotAlmostEqual(a, b)</code>	<code>round(a-b, 7) != 0</code>
<code>assertGreater(a, b)</code>	<code>a > b</code>
<code>assertGreaterEqual(a, b)</code>	<code>a >= b</code>
<code>assertLess(a, b)</code>	<code>a < b</code>
<code>assertLessEqual(a, b)</code>	<code>a <= b</code>
<code>assertRegexpMatches(s, r)</code>	<code>r.search(s)</code>
<code>assertNotRegexpMatches(s, r)</code>	<code>not r.search(s)</code>
<code>assertItemsEqual(a, b)</code>	<code>sorted(a) == sorted(b)</code> and works with unhashable objs
<code>assertDictContainsSubset(a, b)</code>	all the key/value pairs in <code>a</code> exist in <code>b</code>

Test Suite and Test Runner

Test suites are implemented by the `TestSuite` class. This class allows individual tests and test suites to be aggregated; when the suite is executed, all tests added directly to the suite and in “child” test suites are run.

A test runner is an object that provides a single method, `run()`, which accepts a `TestCase` or `TestSuite` object as a parameter, and returns a result object. The class `TestResult` is provided for use as the result object. `unittest` provides the `TextTestRunner` as an example test runner which reports test results on the standard error stream by default. Alternate runners can be implemented for other environments (such as graphical environments) without any need to derive from a specific class.

A Basic Example of Unittest

```
import unittest

class TestStringMethods(unittest.TestCase):

    def test_upper(self):
        self.assertEqual('foo'.upper(), 'FOO')

    def test_isupper(self):
        self.assertTrue('FOO'.isupper())
        self.assertFalse('Foo'.isupper())

    def test_split(self):
        s = 'hello world'
        self.assertEqual(s.split(), ['hello', 'world'])
        # check that s.split fails when the separator is not a string
        with self.assertRaises(TypeError):
            s.split(2)

suite = unittest.TestLoader().loadTestsFromTestCase(TestStringMethods)
unittest.TextTestRunner(verbosity=2).run(suite)
```

A Basic Example of Unittest

The final block shows the creation of a **TestSuite** that contains all the defined test methods and how those tests can be executed using a **TestRunner**.

The script produces an output that looks like this:

```
test_isupper (__main__.TestStringMethods) ... ok
test_split (__main__.TestStringMethods) ... ok
test_upper (__main__.TestStringMethods) ... ok
```

Ran 3 tests in 0.001s

OK

A Basic Example of Unittest

```
suite = unittest.TestLoader().loadTestsFromTestCase(TestStringMethods)
```

This adds to the suite all the methods which are called with a name that starts with the word “test”.

We can add just some of them creating a **TestSuite** class and adding only the methods that we would like to have runned by the test:

```
suite = unittest.TestSuite()  
suite.addTest(TestStringMethods('test_upper'))  
suite.addTest(TestStringMethods('test_isupper'))
```

Command-Line Interface

The unittest module can be used from the command line to run tests from modules, classes or even individual test methods:

```
python -m unittest test_module1 test_module2  
python -m unittest test_module.TestCase  
python -m unittest test_module.TestCase.test_method
```

It is possible to find and run all the test in the sub-directory of a folder:

```
python -m unittest discover -s project_directory -p "test*.py"
```

Test Fixture

Such test cases can be numerous, and their set-up can be repetitive.

Luckily, the set-up code can be implemented in the **setUp()** which will be automatically call by the framework when we run the test before running each test function. Similarly, we can provide a **tearDown()** method that tidies up after the **runTest()** method has been run.

The operations that are performed during the set-up and cleanup are called test fixture.

Test Fixture

```
import unittest

def fib(n):
    return 1 if n<=2 else fib(n-1)+fib(n-2)

class TestFib(unittest.TestCase):

    def setUp(self):
        self.n = 10
    def tearDown(self):
        del self.n

    def test_fib_assert_equal(self):
        self.assertEqual(fib(self.n), 55)
    def test_fib_assert_true(self):
        self.assertTrue(fib(self.n) == 55)

suite = unittest.TestLoader().loadTestsFromTestCase(TestFib)
unittest.TextTestRunner(verbosity=2).run(suite)
```

Skipping Tests

Unittest supports skipping individual test methods and even whole classes of tests. In addition, it supports marking a test as an “expected failure,” a test that is broken and will fail, but shouldn’t be counted as a failure on a **TestResult**.

You can skip an entire test class adding an apposite decorator:

```
@unittest.skip("showing class skipping")
class MySkippedTestCase(unittest.TestCase):
    def test_not_run(self):
        pass
```

Or only some specified function as in the following example.

Skipping Tests

```
import numpy
import unittest
import sys

class MyTestCase(unittest.TestCase):

    @unittest.skip("demonstrating skipping")
    def test_nothing(self):
        self.fail("shouldn't happen")

    @unittest.skipIf(numpy.__version__ < (1, 3),
                   "not supported in this library version")
    def test_format(self):
        # Tests that work for only a certain version of the library.
        pass

    @unittest.skipUnless(sys.platform.startswith("win"), "requires Windows")
    def test_windows_support(self):
        # windows specific testing code
        Pass

suite = unittest.TestLoader().loadTestsFromTestCase(MyTestCase)
unittest.TextTestRunner(verbosity=2).run(suite)
```

Skipping Tests

The output of this test is:

```
test_format (__main__.MyTestCase) ... skipped 'not supported in this library version'  
test_nothing (__main__.MyTestCase) ... skipped 'demonstrating skipping'  
test_windows_support (__main__.MyTestCase) ... skipped 'requires Windows'
```

Ran 3 tests in 0.005s

OK (skipped=3)

Expected Failure

It is possible to mark a test as an “expected failure,” a test that is broken and will fail, but shouldn’t be counted as a failure on a **TestResult**. It is sufficient using the apposite decorator.

```
import unittest

class ExpectedFailureTestCase(unittest.TestCase):
    @unittest.expectedFailure
    def test_fail(self):
        self.assertEqual(1, 0, "broken")

suite = unittest.TestLoader().loadTestsFromTestCase(ExpectedFailureTestCase)
unittest.TextTestRunner(verbosity=2).run(suite)
```

Git Testing with Continuous Integration

Continuous Integration (CI)

CI allows automating the execution of tests on different platforms/installations

GitLab offers a built-in continuous integration and delivery tool called **GitLab CI**

When a new commit is pushed to the repository, GitLab will use its CI runner to execute the test suite against the code in an isolated Docker container

Setting Up CI/CD on GitLab

To have a working CI you need to:

- add `.gitlab-ci.yml` to the root directory of your repository
- configure a *runner*

The `.gitlab-ci.yml` file tells the GitLab runner what to do. By default, it runs a pipeline with three stages: build, test, and deploy.

The Runner is the process that will trigger the CI pipeline after each commit or push.

A green (if all the tests are passed) or red checkmarker will be associated to the given commit. It is then possible to explore the test reports from the GitLab interface

Creating the `.gitlab-ci.yml` Configuration File

```
image: python:3.5

variables:
  PIP_CACHE_DIR: "$CI_PROJECT_DIR/.cache/pip"

cache:
  paths:
    - .cache/pip
    - venv/

before_script:
  - python -V          # Print out python version for debugging
  - pip install virtualenv
  - virtualenv venv
  - source venv/bin/activate
  - pip install -r requirements.txt

test:
  only:
    - master
  script:
    - python -m unittest discover -s tests
```

Configure a Runner

If you use GitLab.com you can use the **Shared Runners** provided by GitLab Inc.

These are special virtual machines that run on GitLab's infrastructure and can build any project.

To enable the Shared Runners you have to go to your project's

Settings → CI/CD and click Enable shared runners.

The Requirements File

The requirements file contains the number (and eventually the version) of the libraries that are needed to execute the code.

For example, to run the code in the examples of this lecture, the only required library that has to be installed is numpy.

Therefore, we have to have a file called “requirements.txt” which will contain just a single row:

numpy
